# DISTRIBUTION OF FISH EGGS AND LARVAE, TEMPERATURE, AND SALINITY IN THE GEORGES BANK-GULF OF MAINE AREA, 1953 

by<br>Robert R. Marak ${ }^{2}$ and John B. Colton, Jr.<br>Fishery Research Biologists<br>Bureau of Commercial Fisheries<br>U. S. Fish and Wildlife Service<br>Woods Hole, Massachusetts

#### Abstract

Basic data on the distribution of fish eggs and larvae in the Georges Bank-Gulf of Maine area were collected on surveys made by the Bureau of Commercial Fisheries research vessel Albatross $/ I /$ during the spring of 1953. The data are presented in tabular and graphic form. The methods and operational procedures pertinent to these surveys are given. Plots and tables of surface temperature and salinity are also included.

## INTRODUCTION

A program to study the early life history of haddock on Georges Bank, Browns Bank, and in the Gulf of Maine was started at the Bureau of Commercial Fisheries Biological Laboratory, Woods Hole, Massachusetts, in the spring of 1953. It was the purpose of this program to attempt to relate the pattern of drift of eggs and larvae to the success of the year class. Fish egg and larvae surveys were undertaken to locate centers of abundance of haddock eggs and larvae and to trace their movements during the early, and presumably critical, months of their existence in relation to time, space, and ecological conditions. The purposes of this report are to describe the methods used and to present basic data on the distribution of fish eggs and larvae, temperature, and salinity during the spring of 1953. To avoid confusion all young fish (prolarvae, postlarvae, juveniles) are referred to as larvae. A list of species of fish eggs and larvae (with species code letters used in the tables) collected during the surveys of 1953 is given in table 1.

Data for temperature and salinityobservations in relation to 1 -meter tows and Hardy Plankton Recorder gauze sections are given in tables 2 , 3 , and 4.

[^0]
## COLLECTION OF DATA

Three cruises were made during the spring of 1953 by the Albatross III: cruise no. 46, March 19 to April 2; cruise no. 48, April 24 to May 8; and cruise no. 50, May 25 to June 3. The cruises were planned so the area of investigation would be covered twice in approximately 14 days to make possible the observation of any rapid changes that might affect the eggs and larvae.

The procedure involved continuous towing of Hardy Plankton Recorders (Hardy, 1936 and 1939), bathythermograph lowerings, surface temperature and salinity observations, driftbottle releases, and surface tows withal-meter net.

## Cruise Plan

With the ship stopped, the number of the gauze division at the bottom of the tunnel was noted and the recorders lowered to the proper marks on the towing cables. A Loran fix was taken, and the ship was brought promptly to 10 knots (normal towing speed). Every hour a bathythermograph lowering was made and a surface temperature was taken by bucket thermometer. When time permitted, a water sample was taken for a salinity determination, concurrent with the surface-temperature observation. Drift bottles were released every 3 hours or approximately 30 miles apart. Twelve bottles were released at each station; 6 were ballasted with sand to float vertically with the necks just breaking the surface, thus minimizing the wind effect,
and the remainder unballasted. Positions of bottle releases and recoveries have been published by Bumpus and Day (1957). Every 12 hours, the ship was stopped, a fix taken, and both recorders checked. The highest number appearing on the gauze in the tunnel was noted, and the gauze wound manually to the next division. At this time, a surface tow was taken with a 1 -meter net. Every 48 hours, the gauze roll was removed, a new one loaded, and the paired towing straps replaced. Torsional fatigue rapidly reduced the breaking stress of the towing wire and paired straps and necessitated the precautions outlined. Details and specifications of the silk, wire rope, and so on, and methods of loading and handling the recorders can be obtained from the Oceanographic Laboratory, Scottish Marine Biological Association, Edinburgh, Scotland. Every 96 hours, 2 fathoms were cut from the outboard end of the towing cable, and the thimble replaced. After 8 days, the towing wires were turned end for end on the winch. At the end of 16 days, the towing wires were replaced.

## Operation of the Hardy Plankton Recorder

One recorder was towed at the surface and one at 10 meters. A $1 / 2$-inch square nosepiece was used, and the propeller pitch was set for a gauze rate of roughly 2 inches per 5 miles of tow at an average towing speed of 10 knots. The gauze ( 60 meshes per inch silk) was made in 100 2-inch sections, allowing continuous towing
for 500 miles without reloading. The time neces sary to haul the recorders, advance or change the gauzes, take a l-meter net haul, and reset the recorders seldom exceeded $1 / 2$ hour.

## One-Meter Net Tows

Qualitative samples of fish eggs and larvae for hatching and identification purposes were obtained by a l-meter net (No. O silk) towed on the surface (see figs. 1, 2, and 3) for 10-15 minutes at the slowest possible speed. The spawning seasons and size ranges of the eggs of haddock (Melanogrammus aeglefinus), cod (Gadus morhua), and witch flounder (Glyptocepholus cynoglossus) overlap. A few days before hatching, however, the pigment pattern characteristic of the larva appears, and the eggs of the three species can then be distinguished. A portion of the fish eggs was immediately separated from the other plankton and transferred to hatching jars placed in a constant-temperature bath maintained at approximately $8^{\circ} \mathrm{C}$. The remainder of the eggs, all larval fish, and a representative sample of other plankton were preserved in 5 -percent formalin.

The water in the hatching jars was changed once daily. The eggs were stirred and the temperature recorded three times a day. After the majority of the eggs had hatched, or reached a stage of development where they were readily identifiable, they were preserved in separate vials in 5 -percent formalin.

## LABORATORY EXAMINATION OF SAMPLES

## One-Meter Net Tows

At the completion of a cruise, the eggs and larvae collected in the surface hauls with the 1 -meter net were examined in detail. The latestage eggs and recently hatched larvae from the hatching jars were examined, and numbers and proportions of individuals of each species determined. All eggs preserved at the time of capture were measured, counted, and "staged", i.e., the stage of development determined. The larvae were counted and measured. Measurements of egg diameters and hatching length of the various species were made to the nearest 0.01 mm . with an ocular micrometer. The larger larvae were measured to the nearest millimeter. Some eggs were not staged because of their extreme opaqueness, and larvae in poor condition could not be accurately measured. The data for l-meter net tows taken on cruise nos. 46, 48, and 50 are included in tables 5-7.

Six stages, which divided the incubation period into approximately equal periods of time, were specified to enable us to estimate the age of eggs at various locations:

Stage I.--From fertilization to the formation of the early blastodermal cap.

Stage II.--From the completed blastodermal cap to the development of the segmentation cavity.

Stage III.--From the appearance of the early embryonic axis to the approach of the germinal ring to an equatorial position.

Stage IV.--From the equatorial position of the germinal ring to just before blastopore closure.

Stage V.--From blastopore closure (half circle) to $\overline{a l}$ most full circle (scattered pigmentation).

Stage VI.--From the formation of the characteristic pigment pattern to hatching.

Distinguishing features of embryonic development in the six stages and the age in hours and days for eggs developing at $38^{\circ} \mathrm{F}$. are shown in figure 4.

The species composition of eggs at each 1-meter net station served as a guide in determining the proportion of each of the species of eggs picked up by the recorders on runs in the general vicinity of these stations. Thus, if it were found that at a certain station 70 percent of the eggs were cod and 30 percent haddock, this ratio was used in the species allocation of eggs on the individual 2 -inch sections of gauze in this area. It was only necessary to do this for stages $I-V$ cod and haddock eggs, as
the stage VI eggs usually could be separated by pigmentation. This served as a check on the species composition as determined by the two sampling methods.

Little difficulty was encountered in the identification of other fish eggs. Their characteristic size, taxonomical and distributional (both in time and space) differences made separation relatively simple.

The identification of larval forms of fishoften was difficult because of the lack of definite pigment patterns at certain stages of development and because of the crushed condition of some specimens due to impact on the recorder gauzes. In the postlarval stages, especially of haddock, cod, and pollock, where the fish are undergoing a transition from the larval to the mature form, pigmentation patterns tend to fuse making identification extremely difficult. Larval fish from the time of hatching to about 10 mm . can usually be separated by their distinctive pigmentation pattern. Fry of about 30 mm . and larger usually had assumed adult characteristics.

We found that vertebral counts, especially of the abdominal vertebrae, served as anexcellent means of separating postlarval gadoids.

After clearing and staining, using the technique described by Hollister (1934) with some modifications described by Clothier (1950), the following vertebral counts were made:

Total vertebrae.--Total number of vertebrae, excluding the urostyle (atlas through penultimate).

Abdominal vertebrae.--Anterior vertebrae (without haemal spines). In gadoids this is synonymous with the number of vertebrae without haemal arches.

Caudal vertebrae.--Posterior vertebrae (with haemal spines). In gadoids this is synonymous with the number of vertebrae having haemal arches.

This method of identification has proved extremely helpful in the classification of samples taken in the plankton recorder where there is a tendency for the specimens to be crushed or flattened beyond recognition. Fortunately, the vertebrae remain intact, and it is usually possible to make a count of abdominal vertebrae.

## Hardy Plankton Recorder

In analyzing the material collected by the Hardy Plankton Recorders the following procedures were followed:

The gauzes were cut into divisions of four sections to facilitate handling and examination. The covering gauze was folded back, and both

Figure 4.--Stages of development of haddock and cod eggs from fertilization to hatching.
the gauzes were viewed with a specially designed traversing stereomicroscope using l0X magnification (fig. 5). With this magnification it was possible to cover a 2 -inch section of the filtering gauze and its corresponding section of covering gauze with two traverses of the microscope.

All fish eggs and larvae were counted and put in vials numbered similarly to the 2 -inch gauze section. All eggs, except those in very poor condition, were then staged, measured, and identified using a compound microscope. Because the majority of the eggs were flattened, exact measurements were impossible; therefore, the sizes are not listed in the tables. These measurements were used only foridentification purposes. Some eggs in an extremely
crushed condition were not staged. All larvae, except the badly crushed specimens, were measured and identified. The very small larvae were measured to the nearest 0.01 mm , and the larger ones to the nearest millimeter. Tables $8-10$ contain the surface and 10 -meter data collected by the Hardy Plankton Recorders during cruise nos. 46,48 , and 50 .

A track chart of the cruise was prepared, showing time and position of each Loran fix, locations of 1 -meter net tows, locations of drift-bottle releases, and start and finish of the recorder runs.

The distance traversed for each 2 -inch section of exposed gauze was obtained by dividing the total distance run by the number of 2 -inch

Figure 5.-- Traversing microscope used for examining Recorder gauzes.
sections exposed. The track charts were then completed showing locations where individual gauze sections were exposed in recorders both at the surface and at 10 meters (figs. 6-11). Tables 2, 3, and 4 give date, time, and position for reference gauze sections. The section equivalent varied slightly with individual recorders and among distances covered (see tables 11-13). Because the section equivalent varied, the number of eggs and larvae were converted to numbers per 5 miles of tow.

Throughout our work we use numbers per 5 miles of tow as a unit of abundance. In this distance at normal towing speeds, the recorder with a $1 / 2$-inch square opening will theoretically filter 0.30 cubic meters of water per mile. To convert numbers per miles to numbers per cubic meter, it is necessary to multiply by a factor of 0.66 .

All numbers listed in tables $8-10$ have been converted to numbers per 5 miles of tow and rounded to the nearest whole number.

It will be realized, from the tables $8-10$, that the numbers of eggs and larvae in individual samples were very low. Experience has shown,
however, that the samples provide excellent material for quantitative studies of distribution and of fluctuations in abundance. This has been demonstrated by Colton, Honey, and Temple (1961), Colton and Marak (in press), Colton and Temple (1961), and Henderson (1954).

## Temperature and Salinity

Only surface temperatures were used in the graphic presentation in this report as they were generally found to be indicative of temperatures in the depth of water studied, 10 meters to surface. Observed temperatures were rounded to the nearest whole ${ }^{\circ}$ F., and salinity values were rounded to nearest $0.5 \% 0$ (figs. 1, 2, 3, 12, 13, and 14). Actual temperature and salinity figures may be found in tables 2,3 , and 4.

## Drift Bottles

A detailed analysis of the data obtained from the drift bottles released on these cruises during the spring of 1953 has been reported by Day (1958).
